1. Consider a two-sector growth model in which the representative consumer has the utility function

$$\sum_{t=0}^{\infty} \beta^t \log(c_{it}^{\alpha^i}, c_{2it}^{\alpha^2i}).$$

The investment good is produced according to

$$k_{t+1} = dx_{it}x_{2it}^{\alpha^2},$$

where $$\alpha^i \geq 0$$ and $$\alpha^i + \alpha^2 = 1$$. Feasible consumption/investment plans satisfy the feasibility constraints

$$c_{it} + x_{it} = \phi_i(k_{it}, \ell_{it}) = k_{it},$$
$$c_{2it} + x_{2it} = \phi_2(k_{2it}, \ell_{2it}) = \ell_{2it},$$

where

$$k_{it} + k_{2it} = k_i,$$
$$\ell_{it} + \ell_{2it} = 1.$$

The initial value of $$k_i$$ is $$\bar{k}_0$$. All of the variables specified above are in per capita terms. There is a measure $$L$$ of consumer/workers.

a) Define an equilibrium for this economy.

b) Write out a social planner’s problem for this economy. Explain how solution to this social planner’s problem is related to that of the one-sector social planner’s problem

$$\sum_{t=0}^{\infty} \beta^t \log c_i$$

s.t. $$c_i + k_{i+1} = dk_i^{\alpha^i}$$
$$c_i, k_i \geq 0$$
$$k_0 = \bar{k}_0.$$
[You can write done a proposition or propositions without providing a proof or proofs, but be sure to carefully relate the variables in the two-sector model to the variables in the one-sector model.]

c) Solve the one-sector social planner’s problem in part b. [Recall that the policy function for investment has the form \( k_{t+1}(k_t) = Adk_t^{a_i} \) where \( A \) is a constant that you remember or can determine with a bit of algebra and calculus.]

d) Suppose now that there is a world made up of \( n \) different countries, all with the same technologies and preferences, but with different constant populations, \( L_i \), and with different initial capital-labor ratios \( k_0^i \). Suppose that goods 1 and 2 can be freely traded across countries, but that the investment good cannot be traded. Suppose too that there is no international borrowing. Define an equilibrium for the world economy.

e) State and prove versions of the factor price equalization theorem, the Stolper-Samuelson theorem, the Rybczynski theorem, and the Heckscher-Ohlin theorem for this particular world economy.

f) Let \( s_i = c_i / y_i \) where \( y_i = p_i k_i + p_{2i} = dk_i^{a_i} \) is world GDP per capita. Transform the first-order conditions for the one-sector social planner’s problem in part b into two difference equations in \( k_t \) and \( s_t \). Use the first-order conditions for the consumer’s problem of the equilibrium in part d to show that

\[
\frac{y'_i - y_i}{y_i} = \frac{s_i}{s_{i-1}} \left( \frac{y'_{i-1} - y_{i-1}}{y'_{i-1}} \right) = \frac{s_i}{s_0} \left( \frac{y'_0 - y_0}{y'_0} \right).
\]

g) Use the solution to the one-sector social planner’s problem in part c to solve for \( s_t \). Discuss the economic significance of the result that you obtain.

2. Consider an economy in which the consumption space is the set of functions \( c : R_+ \times R_+ \to R_+ \). In \( c(x,t) \) the index \( x \) denotes the type of good and the index \( t \) denotes the date at which it is consumed. An individual consumer has preferences given by the functional

\[
u(c) = \int_0^\infty e^{-\rho t} \left[ \int_0^\infty \log(c(x,t) + 1) dx \right] dt.
\]

Goods are produced using a single factor of production, labor:

\[ y(x,t) = \ell(x,t)/a(x,t). \]
Each consumer has an endowment of labor equal to 1, and the total number of consumers is fixed at $\ell$. The unit labor requirement $a(x,t)$ is bounded from below, $a(x,t) > \bar{a}(x)$, where

$$\bar{a}(x) = e^{-x}.$$

At $t = 0$ there is a $z(0) > 0$ such that $a(x,0) = e^{-x}$ for all $x < z(0)$ and that $a(x,0) = e^{-2z(0)}$ for all $x \geq z(0)$. There is learning by doing of the form

$$\dot{a}(x,t) = \begin{cases} -\int_0^\infty b(v,t)\ell(v,t)dv & \text{if } a(x,t) > \bar{a}(x) \\ 0 & \text{if } a(x,t) = \bar{a}(x) \end{cases}.$$

Here $\dot{a}(x,t)$ denotes the partial derivative of $a(x,t)$ with respect to $t$ and $b(v,t) = b > 0$ if $a(v,t) > \bar{a}(v)$ and $b(v,t) = 0$ if $a(v,t) = \bar{a}(v)$. There is no borrowing or lending, and there is no storage.

a) Provide a motivation for both the utility function and the production technology described above.

b) Define an equilibrium for this economy. Characterize the equilibrium as much as possible.

c) Consider now a two country world in which the two countries are identical except in their endowments of labor and their initial technology levels. In particular, $z^1(0) > z^2(0)$. There is no borrowing or lending across countries. Define an equilibrium for this economy.

d) Suppose that $z^1(t) > z^2(t)$. Explain carefully and illustrate two of the five qualitatively different possible equilibrium configurations for production, consumption, and trade at time $t$. (To make things easy, assume that $z^1(t)$ and $z^2(t)$ are sufficiently large so that good $x = 0$ is not produced in equilibrium.)

e) Briefly describe the dynamics of this model, explaining the crucial role played by the sizes of the two countries, $\ell^1$ and $\ell^2$. 
3. Consider an economy where the consumers have Dixit-Stiglitz utility functions and solve the problem

$$\max (1-\alpha) \log c_0 + \frac{\alpha}{\rho} \log \int_0^m c(z)^\rho dz$$

$$\text{s.t. } p_0c_0 + \int_0^m p(z)c(z)dz = w\ell + \pi$$

$$c(z) \geq 0.$$  

Here $1 > \alpha > 0$ and $1 > \rho > 0$. Furthermore, $m > 0$ is the measure of firms, which is determined in equilibrium. Suppose that good 0 is produced with the constant-returns production function $y_0 = \ell_0$.

a) Suppose that the producer of good $z$ takes the prices $p(z')$, for $z' \neq z$, as given. Suppose too that this producer has the production function

$$y(z) = \max \left[ x(z)(\ell(z) - f), 0 \right].$$

where $x(z) > 0$ is the firm’s productivity level and $f > 0$. Solve the firm’s profit maximization problem to derive an optimal pricing rule.

b) Suppose that good 0 is produced with the constant-returns production function $y_0 = \ell_0$. Suppose that firm productivities are distributed on the interval $x \geq 1$ according to the Pareto distribution with distribution function

$$F(x) = 1 - x^{-\gamma},$$

where $\gamma > 2$ and $\gamma > \rho/(1-\rho)$. Also suppose that the measure of potential firms is fixed at $\mu$. Define an equilibrium for this economy.

c) Suppose that, in equilibrium not all potential firms actually produce. Find an expression for the productivity of the least productive firm that produces. That is, find a productivity $\bar{x} > 1$ such that no firm with $x(z) < \bar{x}$ produces and all firms with $x(z) \geq \bar{x}$ produce. Relate the measure of firms that produce $m$ to the measure of potential firms $\mu$ and the cutoff $\bar{x}$.

d) Suppose now that there are two countries that engage in trade. Each country $i$, $i = 1, 2$, has a population of $\ell_i$ and a measure of potential firms of $\mu_i$. Firms’ productivities are again distributed according to the Pareto distribution, $F(x) = 1 - x^{-\gamma}$. A firm in country $i$ faces a fixed cost of exporting to country $j$, $j \not= i$, of $f_e$ where $f_i > f_d = f$. Each country also imposes an ad valorem tariff $\tau$ on imports of differentiated goods from the other country. The revenue from these tariffs is
redistributed in lump-sum form to the consumer in that country. Define an equilibrium for this world economy.

e) Suppose that the two countries in part d are symmetric in the sense that $\bar{\ell}_1 = \bar{\ell}_2 = \bar{\ell}$ and $\mu_1 = \mu_2 = \mu$. Explain how to characterize the equilibrium production patterns with a cutoff value, or values, as in part c. [You should explain carefully how to calculate any cutoff values, but you do not actually need to calculate it.] Compare this value, or these values, with that in part c. Draw a graph depicting what happens when a closed economy opens to trade.

f) Discuss the strengths and limitations of this sort of model for accounting for firm-level data on exports.

4. Consider a small open economy whose government borrows from international lenders. In every period, the value of output is

$$y(z) = Z^{1-z} \bar{y}$$

where $1 > Z > 0$ is a constant and $z = 0$ if the government defaults in that period or has defaulted in the past and $\bar{y}$ is a constant. The government’s tax revenue is $\theta y(z)$ where the tax rate $1 > \theta > 0$ is constant. The consumers in the economy consume $c = (1 - \theta)y(z)$. The government is benevolent and makes choices to maximize the expected discounted value of

$$u(c, g) = \log c + \gamma \log g$$

where $\gamma > 0$ and $1 > \beta > 0$ is the discount factor. At the beginning of every period, the state of the economy is $s = (B, z_{-1}, \zeta)$ where $B$ is the level of government debt; $z_{-1} = 0$ if the government has defaulted in the past, and $z_{-1} = 1$ if not, and $\zeta \sim U[0,1]$ is the realization of a sunspot variable. The government first offers $B'$ to international bankers. The intentional bankers have the same discount factor $\beta$ as the government. They are also risk neutral and have deep pockets. These international bankers buy the bonds at a competitive auction that determines a price for $B'$, $q(B', s)$. The government finally chooses to default or not, which determines private consumption $c$. Government spending $g$ is determined by the government’s budget constraint

$$g + zB = \theta y(z) + q(B', s)B'.$$

If the government defaults, setting $z = 0$, then assume that $z_{-1} = 0$ implies $z = 0$ thereafter; that is, the economy suffers from the default penalty $1 - Z$ forever.
Furthermore, \( z_{-1} = 0 \) implies \( q(B', s) = 0 \); that is, the government is permanently excluded from credit markets.

a) Define a recursive equilibrium.

b) Assume that the bankers expect the government to default if \( \zeta > 1 - \pi \) and if such an expectation would be self-fulfilling, where \( 1 \geq \pi \geq 0 \) is an arbitrary constant. Find a level of debt \( \overline{b} \) such that, if \( B \leq \overline{b} \), no default occurs in equilibrium, but that, if \( B > \overline{b} \), default occurs in equilibrium.

c) Suppose that \( B_0 > \overline{b} \), and the government chooses to run down its debt to \( B_T \leq \overline{b} \) in \( T \) periods. Prove that it cannot be optimal to set \( B_T < \overline{b} \). Prove that it is optimal for the government to set \( g_T \) constant as long as \( B > \overline{b} \) and no crisis occurs. Find expressions for \( g_T \) and \( B_T \) that depend on \( B_0 \) and \( T \). Find an expression for the expected discounted value of the utility of running down the debt that starts at \( B_0 \) to \( \overline{b} \) in \( T \) periods. Find the limit of these expressions when \( T = \infty \).

d) Using the answers to part c, write down a formula that determines a value of debt \( \overline{B}(\pi) \) such that the government would choose to default if \( B > \overline{B}(\pi) \) even if international bankers do not expect a default.

e) Using the answers to parts a–d, construct a recursive equilibrium.

f) Use this model to interpret events of the Mexican financial crisis of December 1994 through January 1995. Discuss the strengths and weaknesses of this model.
