1. Consider an economy where the consumers have Dixit-Stiglitz utility functions and solve the problem

\[
\max \ (1 - \alpha) \log c_o + (\alpha / \rho) \log \int_0^m c(v) v^\rho dv \\
\text{s.t.} \ p_o c_o + \int_0^m p(v) c(v) dv = w \bar{\ell} + \pi \\
c(v) \geq 0.
\]

Here \( \pi \) are profits of the firms, which are owned by the consumers.

a) Suppose that the producer of good \( v \) takes the price function \( p(v) \) as given. Suppose too that this producer has the production function

\[
y(v) = \max \left[ z(v) (\ell(v) - f), 0 \right].
\]

Solve the consumer’s profit maximization problem to derive an optimal pricing rule.

b) Suppose that there is a measure \( \mu \) of potential firms. Firm productivities are distributed on the interval \( z \geq 1 \) according to the Pareto distribution with distribution function

\[
F(z) = 1 - z^{-\gamma}.
\]

Define an equilibrium for this economy.

c) Suppose that \( \mu \) is large enough so that not all firms can earn nonnegative profits in equilibrium. Find an expression for the cutoff productivity level \( \bar{z} \) such that firms with productivity \( \bar{z} \) earn zero profits. Find an expression that relates the measure of goods consumed \( m \) to the measure of potential firms \( \mu \) and the cutoff level \( \bar{z} \). Find an expression for profits \( \pi \).

d) Suppose now that there are two countries that engage in free trade. Each country \( i \), \( i = 1, 2 \), has a population of \( \bar{\ell}_i \) and a measure of potential firms of \( \mu_i \). Firms’ productivities are again distributed according to the Pareto distribution, \( F(z) = 1 - z^{-\gamma} \). A firm in country \( i \) faces a fixed cost of exporting to country \( j \), \( j \neq i \), of \( f_x \) where \( f_x > f_d = f \) and an iceberg transportation cost of \( \tau - 1 \geq 0 \). Define an equilibrium for this economy.
e) Suppose now that the two countries in part d are symmetric in the sense that \( \bar{\ell}_1 = \bar{\ell}_2 = \bar{\ell} \) and \( \mu_1 = \mu_2 = \mu \). Suppose too that \( \mu \) is large enough so that not all firms can earn nonnegative profits in equilibrium. Explain now why there are two relevant cutoff levels of firm productivity, \( \bar{z}_d \) and \( \bar{z}_s \). Find expressions for these cutoff productivity levels. Find an expression for profits \( \pi \).

f) Discuss the strengths and weaknesses of this model. In particular: What economic phenomena can this sort of model help to account for? What sort of phenomena can it not account for? How can we modify the model to account for these phenomena?

2. Consider a two-sector growth model in which the representative consumer has the utility function

\[
\sum_{t=0}^{\infty} \beta^t \log(a_1 c_{1t}^b + a_2 c_{2t}^b)^{1/b}.
\]

The investment good is produced according to

\[
k_{t+1} = d(a_1 x_{1t}^b + a_2 x_{2t}^b)^{1/b}.
\]

In particular, the depreciation rate is \( \delta = 1 \). Feasible consumption/investment plans satisfy the feasibility constraints

\[
\begin{align*}
c_{1t} + x_{1t} &= \phi_1(k_{1t}, \ell_{1t}) = k_{1t} \\
c_{2t} + x_{2t} &= \phi_2(k_{2t}, \ell_{2t}) = \ell_{2t},
\end{align*}
\]

where

\[
\begin{align*}
k_{1t} + k_{2t} &= k_t \\
\ell_{1t} + \ell_{2t} &= \ell_t.
\end{align*}
\]

The initial value of \( k_t \) is \( \bar{k}_0 \). \( \ell_t \) is normalized to 1.

a) Define an equilibrium for this economy.

b) Explain how you can reduce the equilibrium conditions of part a to two difference equations in \( k_t \) and \( c_t \) and a transversality condition. Here \( c_t = d(a_1 c_{1t}^b + a_2 c_{2t}^b)^{1/b} \) is aggregate consumption. (You do not need to go through all of the algebra, but you need to explain all of the logical steps carefully.)

c) Suppose now that there is a world made up of two different countries, each with the same technologies and preferences, but with different constant populations, \( L_i = \bar{L}_i \), and with different initial capital-labor ratios \( \bar{k}_0 \). Suppose that goods 1 and 2 can be freely traded across countries, but that the investment good cannot be traded. Suppose too that there is no international borrowing. Define an equilibrium for the world economy.
d) State and prove versions of the factor price equalization theorem, the Stolper-Samuelson theorem, the Rybczynski theorem, and the Heckscher-Ohlin theorem for this particular world economy.

e) Let \( s_t = c_t / y_t \) where \( y_t = p_{1t}k_{1t} + p_{2t} = r_t k_t + w_t = d(a_t k_t^b + a_2) \) is income per capita. Transform the two difference equation in part b into two difference equations in \( k_t \) and \( s_t \). Prove that

\[
\frac{y'_t - y_t}{y_t} = s_{t-1} \left( \frac{y'_{t-1} - y_{t-1}}{y_{t-1}} \right) = s_{t-1} \left( \frac{y'_0 - y_0}{y_0} \right),
\]

where \( y'_t = p_{1t}k'^t + p_{2t} = r_t k'_t + w_t = d(a_t k'^t + a_2) \) is income per capita in country \( i \).

f) Discuss the economic significance of the result in part e.
