

Lecture 11(i)

Announcements

- Midterm results posted next week
- Sections this week will go over worksheet at Canvas on monopoly.
- HW 9 due next week.
- Thanksgiving week schedule (next week)
 - Monday: class as usual for large lectures
 - Wed: no class
 - No discussion sections week of Thanksgiving

Lecture

1. Marginal Revenue of a Monopolist
2. Profit-Maximizing Monopoly
3. Inefficiency of Monopoly

Monopolist and Competitive Firm

How are they similar?

- Both try to maximize
 $\text{profit} = \text{revenue} - \text{costs}$
- So both set quantity where
marginal rev. = marginal cost
($MR = MC$)

How different?

- When competitive firm sells more
unit, price stays the same
 - $\text{Marginal Revenue} = \text{Price}$
 - Same as saying price taker
- When monopoly firm sells more
price falls
 - $\text{Marginal Revenue} < \text{Price}$

Lemonade Stand

Suppose can sell

- 1 at $P = \$1.00$
- 2 at $P = 50\text{¢}$

Sell second one, cash register rings
up 50¢. Is this MR?

No!!!!

Sell one: Revenue = \$1.00

Sell two: Revenue = .50 + .50
= \$1

So marginal revenue = 0!

(Note: this is uniform price monopoly.
Things are different if can price
discriminate)

Widget Monopoly in Econland

S1-S3 and S5-S10 deceased.

S4 has monopoly.

One change: now she can produce as many widgets as she wants at $ATC = 4$. (So $MC = 4$ too)

If perfect competition, then

- $P = 4$
- Note $P = MC$
- $Q = 6$

But with monopoly, need to do something different.

Let's figure out Marginal Revenue

Marginal Revenue of S4

Q	P	Revenue	MR
0	10		
1	9		
2	8		
3	7		
4	6		
5	5		
6	4		
7	3		
8	2		
9	1		

Rules for MR of **linear demand**

- vertical intercept same as demand
- horizontal intercept is halfway

Picture is all you need for this class.
But if you like an equation...

$$\text{Rev} = P \times Q$$

$$= (10 - Q) \times Q$$

$$= 10Q - Q^2$$

Marginal Revenue is slope

$$\text{MR} = 10 - 2Q$$

What if demand looked like this?

So let's go back to S4's problem
and figure out what she should do.

Put in MC to find optimal output

- Profit maximizing $Q = 3$
- Price that goes with this is $P^M = \$7$
- Profit = $[P - ATC] * Q = [7 - 4] * 3 = 9$
- See it on graph

Check that this is profit maximizing:

Q	P	Rev	Cost	Profit
1	9			
2	8			
3	7			
4	6			
5	5			

What if demand looked like this and $MC = 2$? Figure out the monopoly price and quantity.

Inefficiency of Monopoly

Just like a \$3 tax,
But monopolist gets tax revenue!

	Comp.	Monopoly	Change
Q	6	3	-3
P	4	7	+3
CS	18	4.5	-13.5
PS	0	9	9
TS	18	13.5	-4.5

1. Monopoly results in a loss of CS of 13.5 from the higher price.
2. Part is a **transfer** from consumers to the firm. Called a **monopoly rent**

3. Part of consumer loss is deadweight loss of -4.5. Too little output (condition 3 violation).

First Welfare Theorem does not hold when we have monopoly.

4. Can have additional social costs: **Monopoly Rent Seeking Behavior**
Efforts to secure a monopoly

Example in Econland. Suppose give monopoly to first person in line. Suppose time costs \$1 hour. In equilibrium one person gets in line for 9 hours. All the monopoly rent is **dissipated**

In real world:

- Use of resources like the legal and patent system to keep out rivals.
 - Time spent on lawyers is social waste (opportunity cost)

- Entry of too many real estate agents.
 - Try to get the monopoly rent of too high a commission. But may end up selling only a few houses a year.
 - Wait. Where is the monopoly?
Control of Multiple Listing Service (MLS)
