

Lecture 9(ii)

Announcements

- Work on “Consumer Theory” worksheet for recitation
- Vote on 3 policy platforms at week 10 at Canvas. (need to do this to get bonus points for HW 8)
- Office hours today: 1:30-3:25 (4-135 Hanson)

Lecture

1. Review Cost table from last class, to work out case of:
U-Shaped average cost
2. Constant returns to scale
3. Economies of Scale
4. Examples of Wal-Mart and Amazon
5. **Short-run** Supply of Competitive Firm

Cost Table of S11

Q	FC	VC	TC	MC	A F C	A V C	A T C
0	4	0	4	2			
1	4	2	6	4	4	2	6
2	4	6	10	6	2	3	5
3	4	12	16	8	1.33	4	5.33
4	4	20	24		1	5	6

C for “cost,” **F** for “fixed,”
V for “variable,” **T** for “total,”
A for “average,” **M** for “marginal.”

S11's Cost Structure Example of U-Shaped Cost Curve

Points of interest.

1. For $Q < 2$, ATC falling

Region of:

Increasing returns to Scale

(also called economies of scale)

2. For $Q > 2$, ATC rising

Region of:

Decreasing returns to scale

(also called diseconomies of scale.)

3. $Q = 2$, Minimum Average Cost

Facts:

$Q < 2$, $MC < ATC$ and ATC falling

$Q > 2$, $MC > ATC$ and ATC rising

$Q = 2$, $MC = ATC$ and at ATC min.

Constant Returns to Scale

As increase production, scale up all inputs in the same proportion. So costs increase proportionately.

Example: Housepainting

S12's Cost Structure

Q	TC	ATC
0	0	-
1	5	5
2	10	5
3	15	5
4	20	5

$$TC = 5Q$$

Graph of S12's Cost Structure

Economies of Scale (Over entire range of Q)

S13 has $FC = 8$ and
constant marginal cost of 2

$$TC = 2Q + 8$$

$$ATC = TC/Q = 2 + 8/Q$$

Q	TC	ATC
0	8	-
1	10	10
2	12	6
3	14	4.7
4	16	4
8	24	3

Graph of S13's Cost Structure

Here ATC is always falling, never turns back up. So decreasing over entire range of Q

Example industries where scale economies are important

Pharmaceuticals

Fixed cost for research
Marginal cost of making pills small compared to AFC

Software: MC quite low relative to AFC. MC when distribute on internet = 0!

Jumbojet passenger planes with more than 500 people. (Airbus 380), \$16 billion in development costs before fly first plane.

Discount Retailing: By maintaining large scale, Wal-Mart has kept average total costs from its logistics low

For example, there are fixed costs to set up a distribution center. By putting many stores close to distribution centers, Wal-Mart enjoys economies of scale (and can keep inventories low and replenish empty shelves quickly. e.g. restocked shelves on 9/11)

Can read about strategy of packing stores close to each other to enjoy economies of density in [my paper](http://www.econ.umn.edu/~holmes/papers/ecta7699.pdf).

<http://www.econ.umn.edu/~holmes/papers/ecta7699.pdf>

f

The paper is technical, so let's just look at the a movie of how Wal-Mart rolled out its store openings

http://www.econ.umn.edu/~holmes/papers/Wal-Mart_Stores_and_RegDCs.wmv

In industries where scale economies are huge relative to the market size, there is only room for a few players. Discount Retailing: Wal-Mart, Target, K-Mart, plus regional players.

Scale Economics in Wal-Mart's Import Distribution System (See Holmes and Singer (2017) at my web site).

China is source of 86 percent of Walmart's ocean container imports

Big story now: Online Shopping
Early thinking on this: would diminish
scale economies because small
retailers could tap into UPS and
FedEX networks.

Turned out to be the opposite!
To get fast delivery, Amazon is
developing its own distribution
system.

Amazon's share of online sales is
increasing as the overall market
grows.

Fixed cost of "last mile"

Amazon's model very different from
Walmart's model.

Wide-Body Jets: Boeing, Airbus.

After the midterm, we will talk about industries where individual firms are large. But first, let's figure out industries where firms are small relative to the market (so firms **take price as given.**)

Supply of Competitive Firm
Takes P as given

Supply of S1?
Easy. $P > 1$ then $Q = 1$
 $P < 1$ then $Q = 0$

Supply of S11?
Harder

Suppose $P = \$7$. What does S11 do? One way to figure this out is through a a table

Profit = Revenues minus Total Cost

Pick Q to maximize profit

Q	R P×Q	Total Cost	Profit R-TC	MC	MR
0	0	4	-4		7
1	7	6	1	3	7
2	14	10	4	5	7
3	21	16	5	7	7
4	28	24	4	9	7

Profit maximizing quantity = 3

If $MR > MC$ produce more to raise profit

If $MR < MC$ produce less

If $MR = MC$? Just right.

Rule for profit maximizing output for a competitive firm:

If produce, set Q where **Marginal Revenue = Marginal Cost**
But check whether worth being open at all. When do this make a distinction between **short run** and **long run**.

Short Run: fixed cost can't be avoided. Have to pay the rent.
(For S11, FC = 4)

S11 can avoid hiring labor, and also buying materials.

When pick output, forget (in short run) about the rent.

Produce as long as $P \geq AVC$

Long Run Can exit the industry (not renew lease.) Produce as long as

$$P \geq ATC$$

Short Run Supply of Competitive Firm

Rule:

- Find quantity such that $P = MC$
- Check that $P \geq AVC$ at that quantity, and then produce there.
-
- Otherwise shut down.

Short Run Supply Curve for S11
